

An options agent that mostly says no.

A language model may propose a trade. Code decides every strike, size and exit, and Alpaca's official CLI places every order. Paper account PA371G5THNUO, \$100,000 start. This page describes the code that is running today.

THE CUSTOMER PROBLEM

Point a language model at a brokerage account and it will always find a trade. It never says no, and it cannot count contracts. Our own first dry run wanted 178 contracts on one idea. Wingspan is built for a developer who wants to hand an LLM an Alpaca account and not babysit it.

ENGINE ONE · CREDIT SPREAD SELLER

Once a day at 10:15 ET, DeepSeek reads 13 liquid names with forty days of price context and answers one question per name: is there a trade, which direction, how sure. It cannot name a strike, a size or an exit, and it cannot place an order.

Code picks the contracts (short strike at 0.15 to 0.30 delta, 30 to 45 days out, at most \$2 wide) and runs five gates: conviction of at least 0.60, one position per name and six open legs at most, a \$3,000 cap per position, the strike rules, and a liquidity floor of ten cents credit with an unwind cost under 1.5 times the credit, so the exit rule cannot stop the trade out on its own entry.

One multi leg limit order goes out at the net credit. Only the filled count is booked; the remainder is cancelled.

Exits run every twenty minutes with no AI: half the credit, or twice the credit after 10:00 ET on two consecutive sweeps, or 21 days to expiry. A spread is closed only when the unwind fills.

ENGINE TWO · SHARE SCALPER

No AI in it. Two rules on SPY and QQQ, mined from six months of minute bars and frozen on August 28. At 10:15 ET it fades a close that overshoots both the session VWAP and the first fifteen minutes' range. At 13:00 ET it follows a QQQ gap larger than 0.8%. Twenty thousand dollars a trade, two trades a day, a 0.7% stop, out after 120 minutes, flat by 15:50 ET, and a \$300 daily loss halt.

ALPACA INFRASTRUCTURE

Account, positions, clock and every order run through the official Alpaca CLI as a subprocess inside the container, pinned to a checksummed release. Each call is journaled with its exit code and latency. A lost reply is looked up by our own client order id before it is called a failure. On any error nothing opens; the one exception is the scalper's end of day flatten, which may fall back to the SDK and says so in the journal. Option chains come from a read only market data sidecar, stock bars from a hosted Alpaca data relay. Railway runs it as cron; the public dashboard renders the rails from the same functions the bot calls.

WHAT WE PROVED BEFORE TRADING

We replayed the September 1 option chains. Eight of the twenty three spreads the open gate would have taken were already past their own stop on the quotes they were picked from. With the liquidity floor: five admitted, zero past the stop. 276 tests.

Disclosure. The harness predates the event (July 2026). Built inside the window: the share scalper and its study, the Railway deployment, the DeepSeek proposer, the dashboard rework, the CLI transport, and the open gate with its cap and liquidity floor. The account was created August 30; nothing else has traded on it.
