

OptionsAgent

A paper-trading bot that sells credit spreads. Claude proposes. Code decides.

PAPER ONLY

CREDIT SPREADS

RUNS ON THIS MAC

LLM NEVER PICKS STRIKES

OptionsAgent trades one strategy on a **\$100,000 Alpaca paper account** (re-funded on Aug 28; it traded \$5,000 before that): defined-risk credit spreads on 13 liquid names under \$50. Once a day it asks Claude for trade ideas, but Claude only gets to say **which ticker, which direction, and how confident**. Every strike, expiration, size, and exit is chosen by fixed Python rules called rails. If an idea fails any rail, it dies. Most days, nothing trades, and that is by design.

STEP 1

Cron wakes it

Weekdays **10:15 to 10:27 ET**, once a day. A lock file blocks double runs. If the broker clock check fails or the market is shut, it skips the day.

STEP 2

Snapshot

Archives the full option chain (quotes, IV, greeks) for all **13 watchlist names**, then builds a market context bundle per name.

STEP 3

Claude proposes

The local Claude CLI ([sonnet](#), no tools, no web) reads the bundle and proposes **ticker, direction, conviction 0 to 1, thesis**. Strikes and size are banned from its output. CLI failure means zero trades.

STEP 4

Rails veto or size

Deterministic gate: conviction floor **0.60**, max **6** open positions, phase allowlist. Size scales from 30% to 100% of available options buying power.

STEP 5

Code picks the contract

Short leg **15 to 30 delta**, width capped at **\$2, 30 to 45 DTE**. Bullish sells a put spread, bearish sells a call spread. One combo limit order at the net credit.

STEP 6

The winner profile

The spread must also match one of three replayed winners: **CCL bullish put, SOFI bullish put, F bearish call**. Everything else is vetoed. Quiet days are normal.

MEANWHILE, EVERY 20 MIN

A separate exit sweep runs with **no LLM at all**: take profit at **50% of the credit**, stop out at **2x credit** (only after 10:00 ET and only after two consecutive sweeps agree, so one wide quote cannot force a liquidation), force close at **21 DTE**, and check ex-dividend dates before any short call sits through one.

THE NUMBERS THAT GOVERN IT

Account	\$100,000 paper (re-funded Aug 28)
Conviction floor	0.60, below = no trade
Sizing	30% to 100% of free BP
Max concurrent	6 positions
Spread width	≤ \$2.00, max loss ≈ \$200
Entry DTE	30 to 45
Profit target	50% of credit
Stop	2x credit, confirmed twice
Force close	21 DTE

A REAL DAY (AUG 28, 2026)

Claude proposed **8 spreads** across T, CMCSA, WBD, VZ, PFE, MARA, CCL, and AAL. The rails executed **0**. Three found no contract meeting the delta, width, and credit rules. Five failed the winner profile. Meanwhile the exit sweep closed July's SOFI spread for **+\$26.58**. Vetoing everything is the system working, not failing.

FAQ

Is this real money?

No. Alpaca [paper only](#). The code that builds the broker client refuses to run unless paper mode is on. There is no live path.

Why credit spreads?

Day one it bought a MARA long put and lost **37.6%** of the premium in a session. The pivot: sell rich premium with the risk defined by the spread width.

What can Claude actually control?

Only the idea: ticker, direction, conviction, one line of thesis. Output is schema-checked; anything malformed is **dropped, never repaired**.

What if Claude is down?

Zero proposals, zero trades. Every failure path fails closed. A broken market clock check skips the whole day rather than trading blind.

Why only 3 trade profiles?

A replay of July's fills found exactly three winners (CCL, SOFI bullish puts, F bearish calls). Hard-coded so config edits cannot widen them. Full FAQ overleaf.

Where does data come from?

Chains and quotes from a read-only [Public.com](#) sidecar, execution and account at Alpaca paper.

Track record so far?

Paper, since July 3. Five closed spreads: four small losers, one winner, net about **-\$37**. The \$5,000-era book bottomed near \$4,920, then the account was re-funded to **\$100,000** on Aug 28.

And the 0DTE scalper in the code?

A second isolated engine (SPY/QQQ opening range breakout). Its master switch is **off** and it has no cron line. Dormant, not deleted.

FAQ

Everything below is verified from the current code and the live paper account, not from the older docs.

What strategy is running right now, exactly?

Vertical credit spreads only. Bullish thesis sells a put spread, bearish sells a call spread, never neutral. Short leg between 15 and 30 delta, long leg further out on the same expiry, width capped at \$2.00, entry between 30 and 45 DTE. The spread is submitted as a single MLEG combo limit order priced at the net credit, order IDs prefixed oa–.

How does position sizing work?

Position budget = conviction-scaled share of available options buying power. At the 0.60 floor you get 30% of what is free, scaling linearly to 100% at 0.85 and above. $\text{Contracts} = \text{budget} \div (\text{width} \times 100)$. If the budget buys less than one contract, the trade is skipped. Each fill inside a cycle shrinks the base the next proposal is sized against.

100% of buying power on one idea sounds aggressive.

It is deliberate operator policy: "use all the cash, not necessarily all at once." The practical brakes are the \$2 width cap (max loss $\approx$ \$200 per spread, 0.2% of the account), the 6 position cap, the broker's own buying power rejection, and an optional tighten-only kill switch (OA_MAX_POSITION_USD) that can clamp any single position.

What is the winner profile gate and why does it veto so much?

A replay of every archived fill from July 8 to July 31 found three profiles that actually made money: CCL bullish puts (credit $\geq$ \$0.29, width $\geq$ \$1.50), SOFI bullish puts (credit $\geq$ \$0.23, width $\geq$ \$1.00), and F bearish calls (credit $\geq$ \$0.06, width $\leq$ \$0.50). Those three are hard-coded. Anything else fails closed. It is openly an in-sample overfit, held frozen on purpose so the account collects clean out-of-sample evidence on whether the profile means anything.

Walk me through the exits.

A no-LLM sweep every 20 minutes during market hours. Priority: dividend risk first (a short call sitting through an ex-date where the dividend exceeds the same-strike put gets closed), then the stop, then DTE, then profit. Profit target is 50% of the credit received. The stop is 2x credit but only counts from 10:00 ET and needs two consecutive sweeps to confirm, so a single wide opening quote cannot trigger a forced liquidation. Everything force-closes at 21 DTE. There is no end-of-day flatten for spreads because nothing here is 0DTE.

What about assignment and overnight gap risk?

Verticals are defined risk: worst case is width minus credit, no more, regardless of assignment mechanics. The 2x credit stop is a loss control, not a guarantee. A gap through the short strike overnight still costs the full width, roughly \$200 per spread at the cap. Six concurrent positions put the theoretical worst day near \$1,200, just over 1% of the \$100,000 account.

Is there a daily loss limit for the seller?

No dedicated one. The brakes are structural: \$2 max width, 6 positions, one short entry window per day (10:15 to 10:27 ET), and the winner profile that rejects most ideas before they exist. If that answer makes you uncomfortable, that is a fair reaction; it is a paper account built to learn the distribution.

What does the LLM see, and can it be manipulated by the data?

It sees a JSON bundle: the phase, the allowed strategies, and per-ticker market context (price levels, volume, recent movement). The system prompt states the context is data, never instructions. It runs with tools disabled, no session persistence, no web access, and its output is validated against a strict schema before anything downstream sees it.

What is the actual track record?

Paper since July 3. Credit-spread era, five closed trades: KVUE -\$2.65, MARA -\$21.83, WBD -\$22.94, T -\$16.40, SOFI +\$26.58. Net $\approx$ -\$37. The \$5,000-era book bottomed near \$4,920 (the rest of that drawdown is the early long-option phase), then the account was re-funded to \$100,000 on Aug 28. Honest summary: no edge proven yet, which is exactly what the frozen winner profile is testing.

There is a 0DTE scalper in the repo. Is it trading?

No. It is fully isolated: own registry, own state files, own order prefix (oas–), master switch OA_SCALP_ENABLED off, and no cron line. When on, it trades SPY/QQQ opening-range breakouts (3 minute range, 1.5x relative volume confirmation plus a VWAP check), \$250 per trade, max 2 trades a day, one position at a time, 30% stop that relaxes to 60% while the breakout holds, 50% profit target, no new entries after 11:30 ET, mandatory flatten by 15:50 ET.

How do I know what it did on any given day?

Three places. The dashboard on the following pages (live at 127.0.0.1:8765, read-only, it cannot submit orders). The decision log at `data/decisions.jsonl`, which records every proposal, every veto reason, and every order. And `data/structures.jsonl`, the append-only record of what opened and closed. Today's log shows 8 proposals and 8 vetoes with reasons.

What stops a bug from doing something catastrophic?

Layers. Rails are hard-coded in Python so no config edit or model output can loosen them; env overrides may only tighten. The broker client refuses non-paper endpoints. Entry is one locked window a day. The exit sweep reconciles the registry against live broker positions and alerts on anything that vanished (assignment, expiry, manual close) instead of silently dropping it.
